Linear Regression Case Study

Najib Mozahem

May 1, 2019

The Dataset

- gpa: overall GPA of the student (this is the dependent variable)
- english: the average grade on all English courses taken by the student (data is taken from a non-English speaking country where the language of instruction in university is English)
- college: whether the student is in the engineering school or the business school (zero means business, one means engineering)
- credits: the total number of credits completed so far by the student
- gender: whether the student is a male or a female (zero means female, one means male)
- attendance: attendance and participation grade last semester
- siblings: Number of brothers and sisters that the student has
- income: family income per year (\$)
- work: records whether the student works full time, part time, or whether the student doesnt work at all.

Continuous Variables

There are two types of independent variables in our dataset, continuous and binary. We start by looking at the continuous variables.

Continuous Variables - Attendance (Scatter plot)

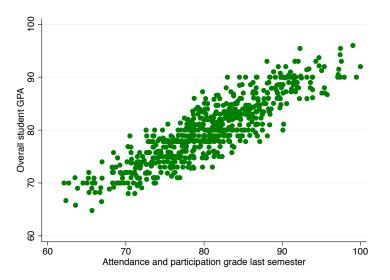

Figure: Scatter plot of GPA and attendance.

Continuous Variables - Attendance (Regression)

Categorical Variables (more than two groups)

The dataset that we are using also contains the variable work. Unlike binary variables, this variable divides the observations into three groups: those that have a full time job, those that have a part time job, and those that have no job at all.

Categorical Variables - Work (Regression)

| Source | SS | df | MS | Numbe | er of obs | = | 677 |

From the previous section, it seems that we need a model that includes the variables attendance, english, the square of english, income, the square of income, siblings, college, gender, and work. We can now fit a multiple regression model that includes all of these variables.

| Source | SS | df | MS | | or ore | = 666 |

- ▶ If you look at the output, you will notice something interesting, and that is that the variable gender is no longer significant.
- ▶ In our dataset, the average GPA for males is 78.76 and the average GPA for females is 81.57.
- ► The average attendance grade for males is 78.62 and that the average attendance grade for females is 83.29.
- ► Therefore, it seems that the difference in GPAs between males and females is due to females attending more.
- ▶ Given the above, we can go ahead and fit a model that does not include gender.

R-squared

We see that the value of R-squared is 0.88, which is high. This means that the model is explaining around 88% of the observed variability in the dependent variable.

Ho: Constant variance
```

Variables: fitted values of gpa

chi2(1) = 5.75Prob > chi2 = 0.0165

Addressing Assumption Violations

- ► Given that we have rejected the assumptions of normality and homoscedasticity, does this mean that we disregard our regression results?
- ► Fortunately no. As mentioned in the theory part, what we can do in this case is to fit the model while telling the statistical software to use robust standard errors.
- ► This way, the assumptions are relaxed and we can have more faith in the resulting model.

Addressing Assumption Violations - Robust Standard Errors

Linear regression

| | | Robust | | | | |

Diagnostics

The next step is to investigate whether there are outliers and influential observations in the dataset.

Outliers

- In order to identify whether there are outliers, we can plot a scatter plot of two variables.
- ► The problem is that this method works when we just have one independent variable.
- ► However, in our model, there are several independent variables.
- ► Fortunately, there is a tool that allows us to work around this problem, and this tool is the added-variable plot.
- What these plots do is that they produce a scatter plot of the dependent variable against each independent variable while accounting for the presence of the other independent variables.

Outliers - Added Variable Plots

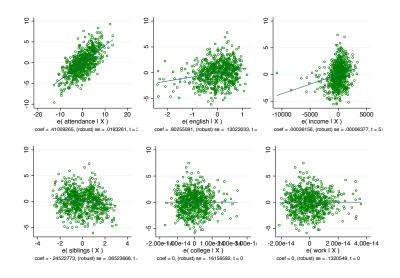

Figure: Added variable plots for each independent variable.

Influential Observations

- ▶ We next investigate whether there are any particularly influential observations in our dataset.
- ▶ We can do this by calculating the DFBETAS, DFFITS, and Cook's D statistic.
- A useful exercise would be to plot the DFFITS and Cook's D on the same plot.

Influential Observations - Plotting DFFITS against Cook's D

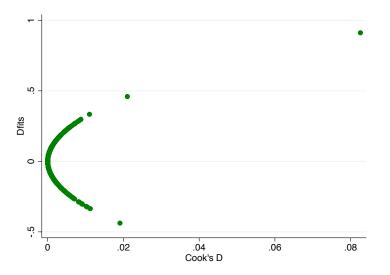

Figure: Plotting DFFITS and Cook's D.

Influential Observations

- ▶ Looking at the figure, we see that there is a single point that seems to be problematic since it has a higher than average values of both statistics.
- ▶ We note that this data point is the only one that has a Cook's D that is greater than 0.08.
- ▶ When discussing the outliers, we noted that there seems to be some outliers with respect to the independent variable income.
- It would be interesting to look at this graph again, but this time while we are paying attention to the value of Cook's D.

Influential Observations - Combining Findings

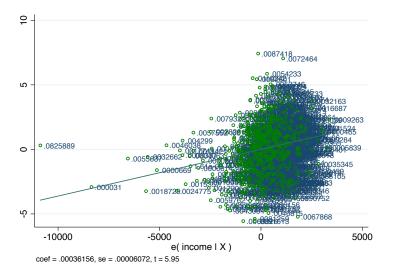

Figure: Added variable plot with Cook's D used as labels.

Influential Observations

- ▶ We now see that the outlier on the left hand side is actually the point that also has a Cook's D that is greater than 0.08.
- ▶ This means that this point is not only an outlier, but it is also influential.
- What do we do with it?
- ► The best thing to do about these points is to fit two models, one that includes all observations, and one that excludes these problematic observations.
- ▶ We can then compare the results.

Influential Observations - Comparing the Models

Table: Comparing estimates of both models
